TABLE OF CONTENTS

x

11	Step 5 – Browser Rendering	Raw data(binary) to human readable
12	Caching and Performance	Speeding up search experiences
13	Security in the Journey	Encrypting and securing data
14	Summary Recap	How all are connected
15	Q&A / Thank You	If any doubt

Ever wondered...

What actually happens when you type a URL like www.google.com and press Enter?

x

Why it matters:

For our existence actually.

In this presentation

How your browser finds the website you're looking for.
What DNS, IP, and HTTP mean in this process.
How data travels across the internet.
How your browser turns code into a web page.

x

x

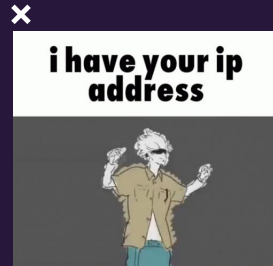

The Journey Begins – From URL to Web Page

Type URL or
Click Link

URL goes to
DNS Server

From server
get IP address

Browser
Sends HTTP
Request

Server
Responds
with Data

Browser
Renders the
Page

+

What is Internet Really

The internet is a global network of interconnected computers and devices that communicate with each other using standardized protocols (like TCP/IP).

The internet's not a cloud, just wires and servers with hard drives storing web pages.
DSL, cable, fiber, or satellite - each connects you to that data, fast or slow.

01

Domain Name System (DNS)

What is DNS?

DNS is like the internet's phonebook – it converts human-friendly domain names (like facebook.com) into IP addresses (like 157.240.22.35) that computers can understand.

Why It's Needed:

Humans remember names (e.g., youtube.com)

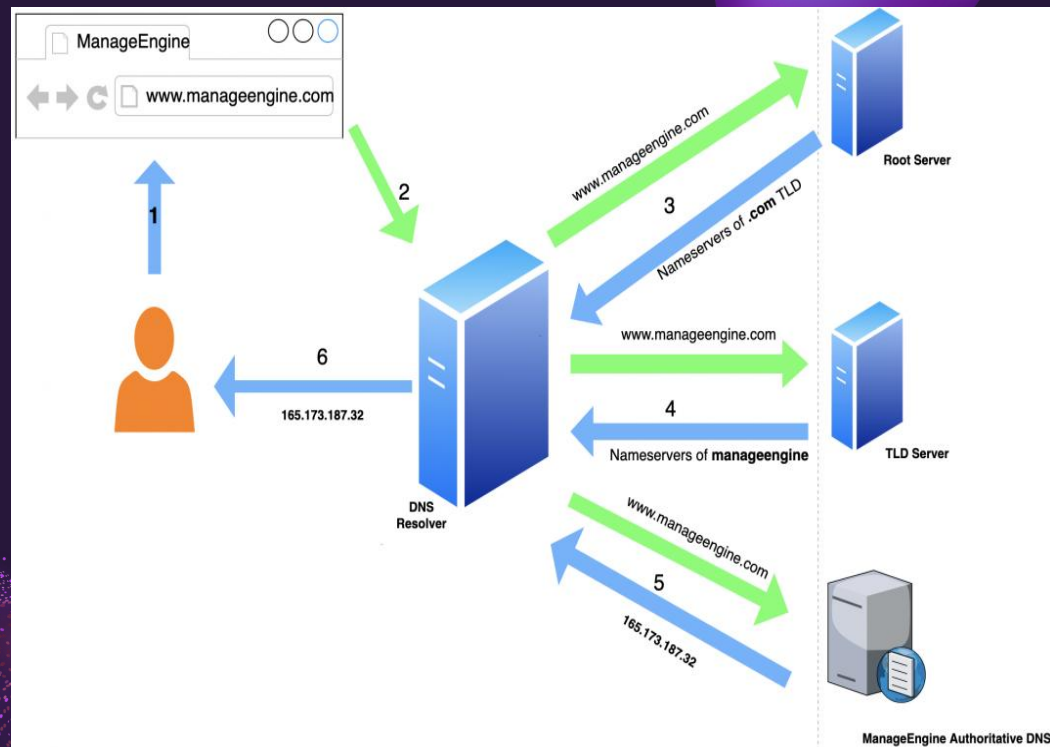

Computers use IP addresses to locate websites

DNS acts as the translator between them

DNS in Action

Step-by-Step Breakdown:

1. You type `www.google.com` and press Enter
2. Browser checks local DNS cache – is the IP already saved?
3. If not, it asks your system's DNS resolver (e.g., from your ISP)
4. Resolver queries:
 - Root DNS Server – where to look next?
 - .com TLD Server – gives Google's DNS info
 - Authoritative DNS Server – gives final IP address (e.g., `142.250.183.132`)
5. The IP is returned to your browser
6. Now, your browser can contact the Google web server

ManageEngine Authoritative DNS

02 IP Address and Routing

What is an IP Address?

An IP address is like the home address of a device on the internet. It tells the internet where to send data.

Example: 142.250.183.132 = Google's server IP

Two types:

IPv4 (e.g., 192.168.1.1)

IPv6 (e.g., 2001:0db8:85a3::8a2e:0370:7334) – newer, longer

How Routing Works

Once the IP is known, the data (your request) travels across many routers and networks

Each router makes a decision: “What’s the best next hop to reach this IP?”

IP Packet Journey

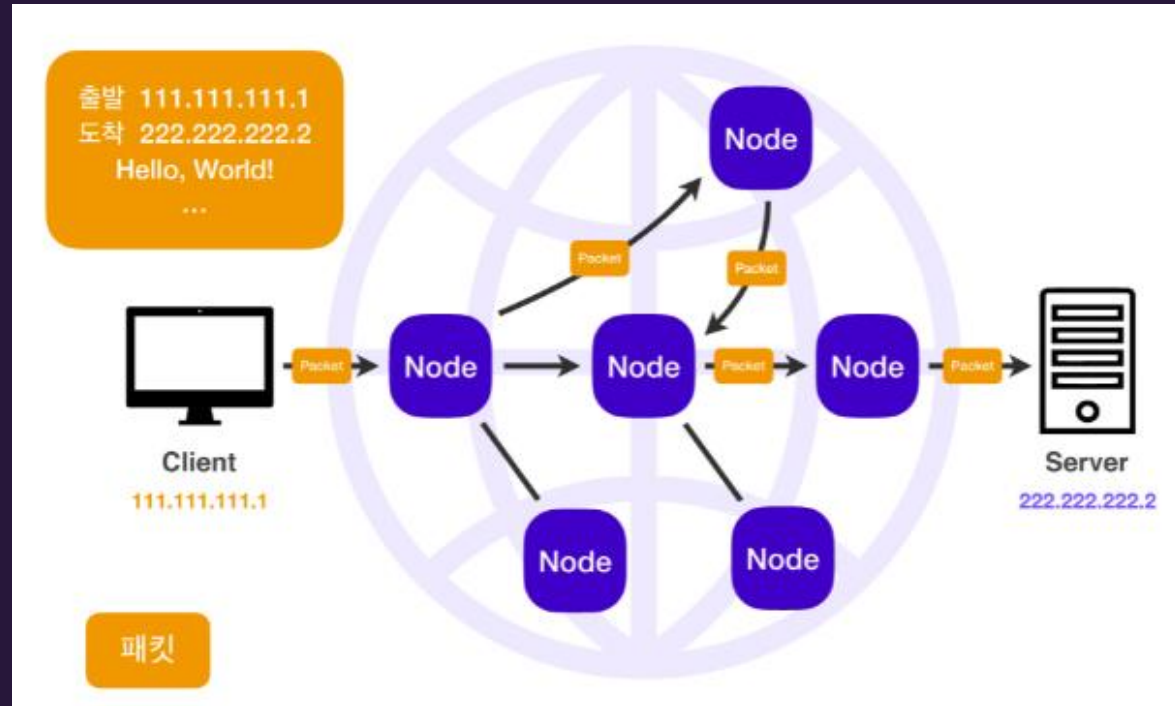

What is a Packet?

A packet is a small chunk of data sent across the internet. Your browser's request is split into multiple packets and sent piece by piece.

How It Works:

- ➔ Each packet contains:
 1. Source & destination IP
 2. Part of the message (e.g., a piece of a webpage)
- ➔ Routers inspect the IP and forward packets toward their destination

03 TCP/IP Protocol

What is TCP/IP?

TCP/IP is the foundation of the internet.

It defines how data is packaged, sent, received, and understood between devices.

4 Key Layers of TCP/IP Model:

Application Layer

Where apps like browsers live

Protocols: HTTP, HTTPS, FTP, DNS

Transport Layer

Ensures reliable data delivery

TCP = Reliable(sites)
UDP = Fast but no guarantee (streaming)

Internet Layer

Handles IP addressing and routing

Protocol: IP

Network Layer

Connects to physical network

(Ethernet, Wi-Fi)

How TCP/IP works

TCP/IP Model

Applications

TCP

IP

Network

REALPARS

x

5. Application – HTTP, FTP, SMTP → Data

4. Transport – TCP/UDP → Segment

3. Network – IP, Routers → Packet

2. Data Link – Ethernet, Switches → Frame

1. Physical – Cables, NICs → Bits

TCP 3 way handshake

Quick Analogy:

Think of TCP/IP like sending a letter:

TCP = careful post office
(guarantees delivery),
IP = address on the envelope.

Before sending data, TCP does:

Client: SYN →

Server: ← SYN-ACK

Client: ACK →

3-Way TCP Handshake

4

HTTP Request

🌐 What is HTTP?

HTTP (HyperText Transfer Protocol) is how your browser talks to web servers to request pages, images, and more.

You type a URL → Browser sends an HTTP GET request

The server receives it, processes it, and prepares a response

🧠 Analogy:

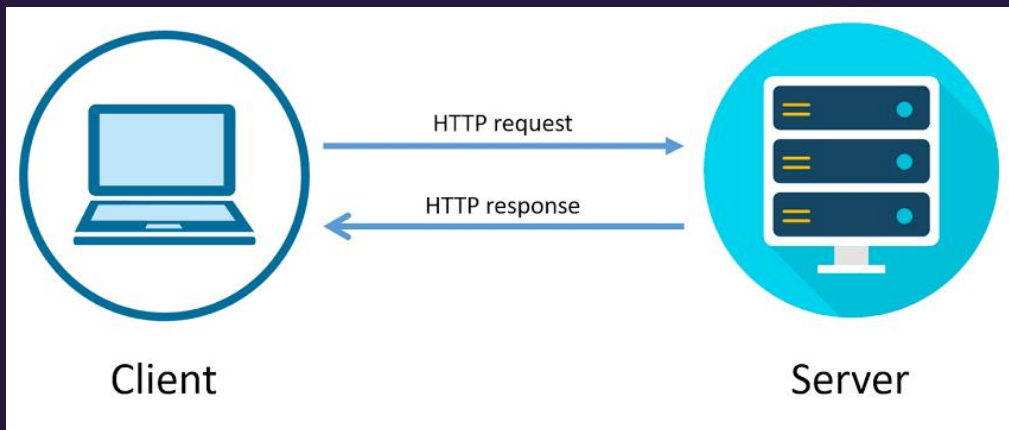

Think of HTTP like a restaurant order:

You (browser) = Customer

HTTP GET = You place an order

Server = Kitchen

HTTP Response = Your food is served
(HTML, CSS, images)

Server Response – Getting the Web Page Back

✉ What Happens After the Request?

The server receives your HTTP request and responds by sending the web page data – usually HTML, CSS, JavaScript, and images.

SERVER RESPONSE CODES

x

📦 Data Returned:

HTML – The structure of the webpage

CSS – Styling (colors, layout, fonts)

JavaScript – Interactive elements

Images, fonts, icons – All downloaded separately

x

Browser Rendering – Turning Code into a Web Page

⚙️ What does the browser do with the data? ×

It takes the HTML, CSS, and JavaScript, and turns it into the visual page you see.

🔄 Rendering Steps (Simplified):

Parse HTML – Browser builds the DOM (Document Object Model)

Parse CSS – Applies styles to the DOM

Run JavaScript – Adds interactivity or modifies content

Layout & Paint – Calculates positions and draws elements ×

Composite – Final page appears on your screen

Caching and Performance – Making the Web Faster

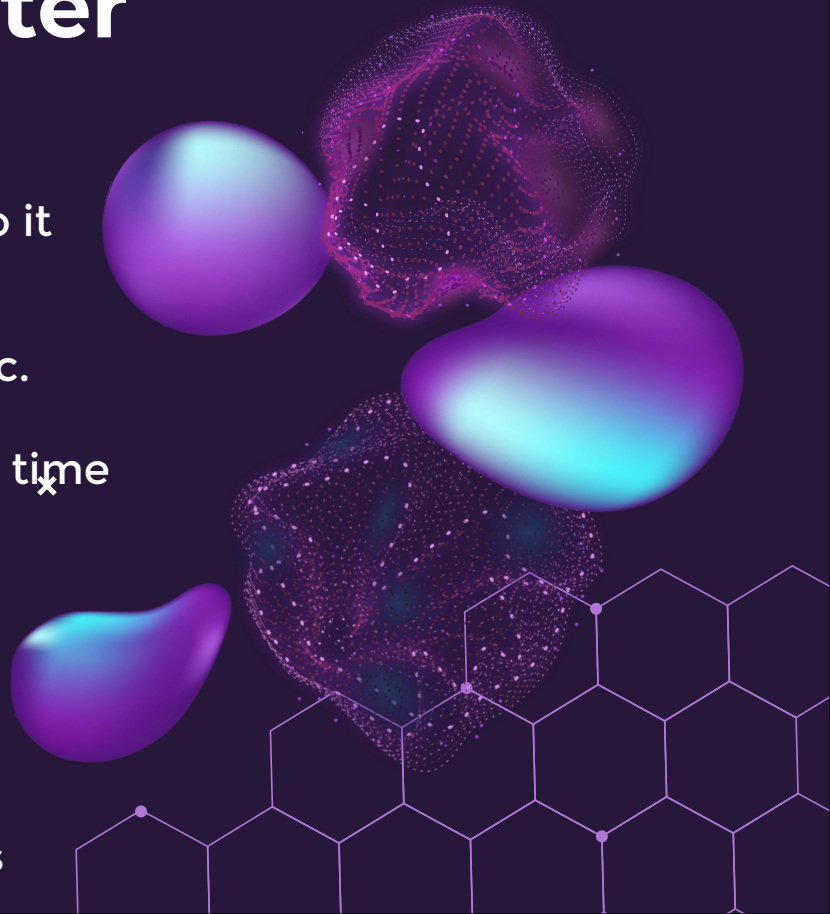

🚀 What is Caching?

Caching means saving copies of web content so it loads faster the next time you visit.

- ❑ Your browser stores HTML, images, CSS, etc. locally
- ❑ If unchanged, it doesn't re-download every time

Types of Caching:

- Browser Cache – Stored on your device
- DNS Cache – Stores recently used IP addresses
- Server-Side Caching – Stores dynamic content on servers
- Content Delivery Networks (CDNs) – Store content on global servers for quicker access

Security in the Journey – Keeping Data Safe

Why is Security Important?

Data travels across the internet, and security ensures that sensitive information doesn't get intercepted or tampered with.

Security Protocols in the Process:

HTTPS (SSL/TLS)

Encrypts data between your browser and the server
Makes sure the server is authentic
You see the padlock icon in the address bar for secure sites

DNSSEC

Protects DNS from being spoofed or hacked
Ensures the IP address returned by DNS is the right one

How SSL/TLS Works:

Browser & server agree on encryption keys

All data exchanged is encrypted

Only the server and browser can decrypt it

Common Threats:

Man-in-the-Middle Attacks(MITM)

Interception of data

x

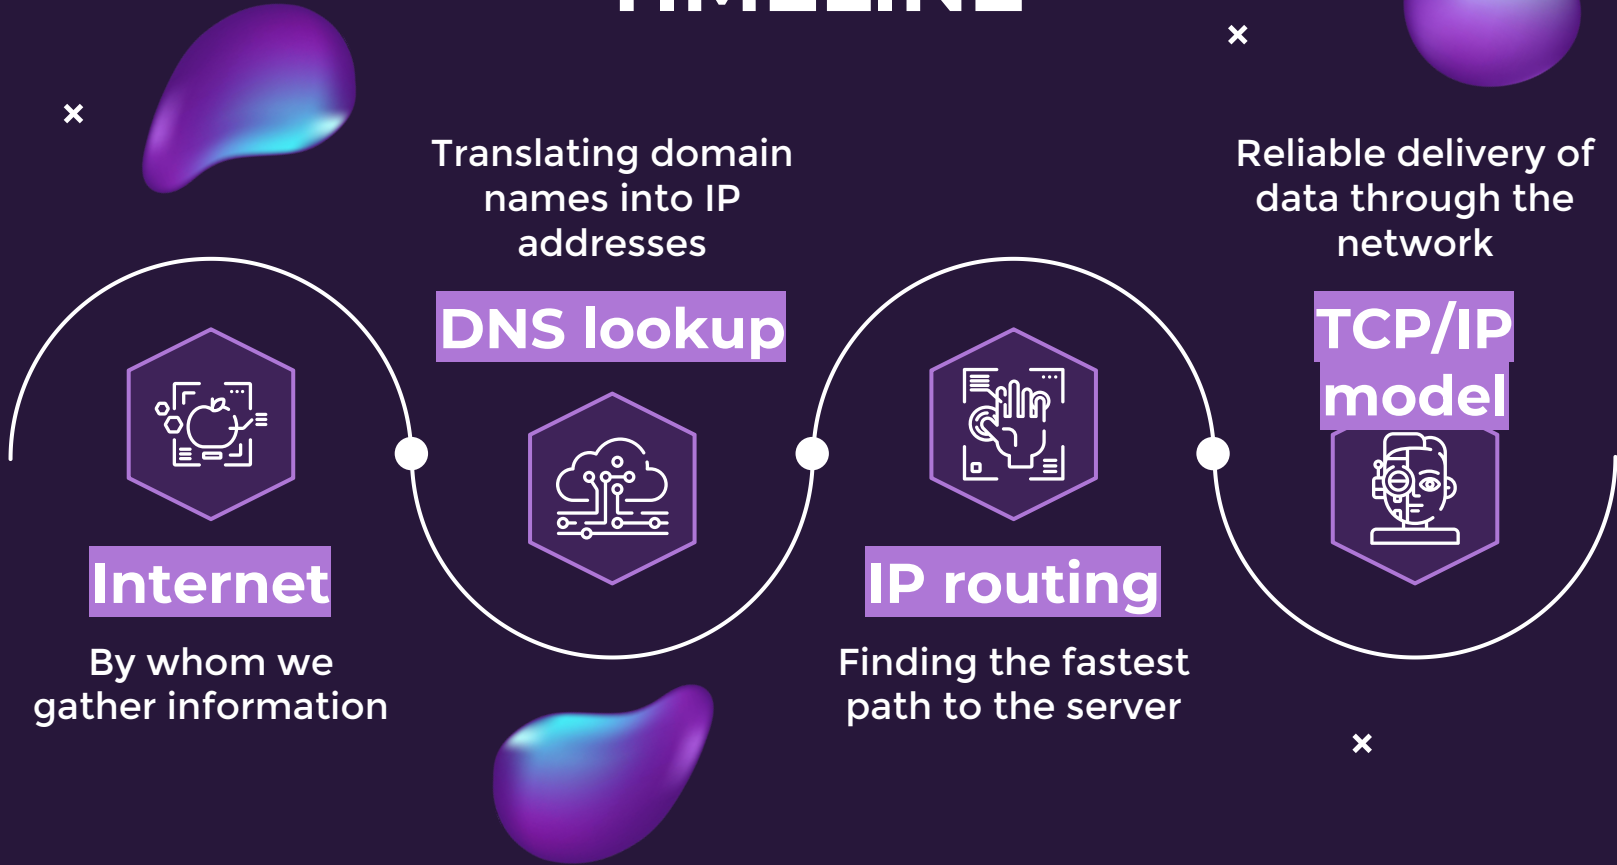

Phishing

Fake websites
tricking you into
revealing info

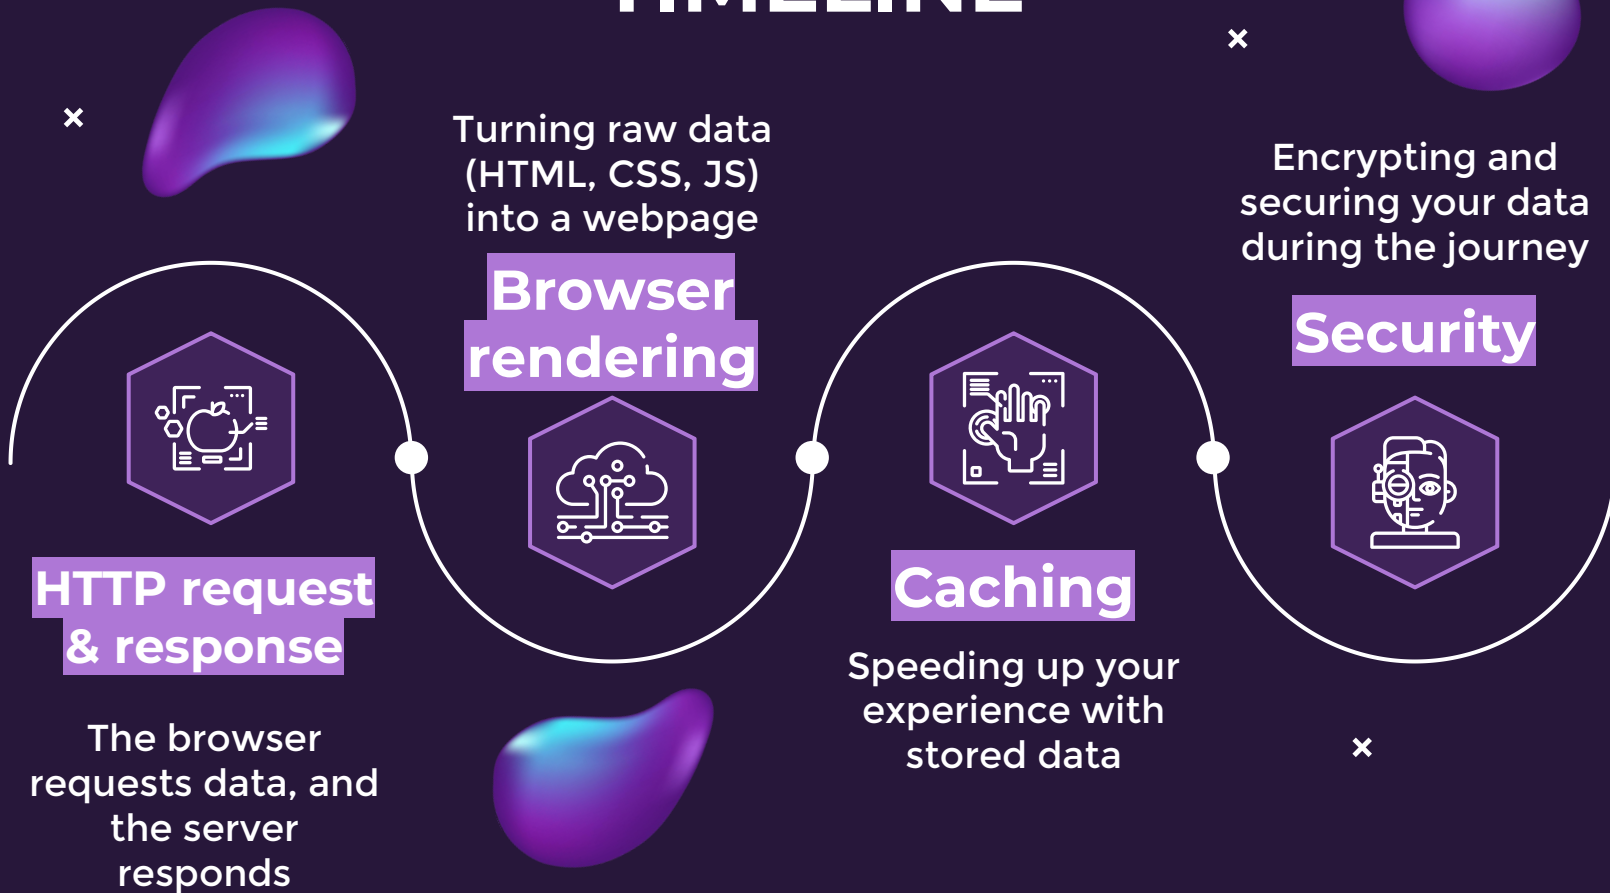

**DNS
Spoofing**

Redirecting
traffic to
malicious sites
